This report documents the impact evaluation of the statewide Low Income Energy Efficiency (LIEE) Program for Program Year (PY) 2000. The participating utilities are Southern California Edison Company (SCE), Pacific Gas and Electric Company (PG&E), San Diego Gas and Electric Company (SDGE), and Southern California Gas Company (SoCalGas).

E.1 PROGRAM BACKGROUND

The LIEE program provides assistance to low-income customer groups throughout the state. The assistance consists of free installation of energy-efficiency measures, energy education, and repair and/or replacement of space heating and evaporative cooling equipment. The program serves an important equity objective in assisting customers who are highly unlikely or unable to participate in other residential conservation programs because of income constraints. This program allows income-eligible customers to receive the benefits of energy conservation without the hardship of making cash investments.

Measures included in the LIEE program (across all service territories but not by all utilities) include:

- Evaporative cooler installation (permanent or portable)
- Relamping
- Weatherization
- Energy education
- Refrigerator replacement
- Porch lamp fixture replacement
- Furnace repair and replacement.

E.2 EVALUATION OVERVIEW

Objective

The primary objective of the impact evaluation was to determine first-year gas and electric impacts resulting from the program.

Evaluation Approach

The impact evaluation utilizes a billing analysis approach. Monthly household electricity and natural gas consumption, both before and after program intervention, are modeled in regression equations as a function of program participation variables and other explanatory variables such as weather, dwelling type, and survey variables. Engineering-based program savings variables were incorporated into the analysis for some measures to develop more detailed measure-specific

results than could be obtained from a simple billing analysis. For the LIEE program, net savings are assumed to be equal to gross savings.

Data

Data used to support the evaluation came from a variety of sources, including:

- Program tracking system data for PY 2000 from each of the utilities;
- Utility billing data—monthly electricity and natural gas use for the January 1999 to October 2001 period;
- Weather data from multiple weather stations in each utility service area; and
- Telephone survey data for a sample of 1000 customers, split evenly between each utility.

E.3 KEY FINDINGS

E.3.1 Total Program Impacts

Table E-1 provides a summary of PY2000 LIEE program impacts. Overall, the program is estimated to be saving 17.5 GWh per year and 1.8 Mth per year. SCE accounts for 39 percent of the program participants and 43 percent on the statewide electric savings. PG&E accounts for 29 percent of the program participants, 50 percent of the electric savings, and 55 percent of the gas savings. SDG&E accounts for 12 percent of the participants, 8 percent of the electric savings, and 11 percent of the gas savings. SoCalGas accounts for 19 percent of the participants and 34 percent of the gas savings.

Table E-1
Summary of PY2000 LIEE Program Annual Impacts

Utility	Participants	Total Impacts		Average Impact per Participant	
		kWh	Therms	kWh	Therms
SCE	48,977	7,504,085		153.2	
PG&E	36,467	8,758,693	1,002,435	240.2	27.5
SDG&E	14,973	1,326,092	191,694	88.6	12.8
SoCalGas	24,271		618,765		25.5
Total	124,688	17,588,871	1,812,894	175.2*	23.9*

* kWh averages exclude SoCalGas and therm averages exclude SCE.

E.3.2 Per Unit Measure Impacts

Per-unit measure savings for non-weather-sensitive measures are presented in Table E-2. These savings were not found to vary significantly by utility. Unit savings are expressed on a per-home basis, except for CFLs, which are expressed on a per-bulb basis. Measure savings vary by dwelling type, with the exception of refrigerators in the PG&E and SDG&E service areas.

Table E-2
Annual Per-Unit Savings – Non-Weather-Sensitive Measures

Measure	Dwelling Type	kWh per Year	Therms per Year
Faucet	Multifamily	41.2	0.9
Aerators	Single Family	48.4	1.4
Low Flow	Multifamily	203.3	6.1
Showerheads	Single Family	239.2	9.1
Water Heater	Multifamily	163.0	4.9
Blankets	Single Family	191.8	7.3
Water Heater	Multifamily	115.3	1.8
Pipe Wrap	Single Family	135.6	2.7
Lighting - CFLs	Multifamily	22.8	
SCE	Single Family	22.4	
Lighting - CFLs	Multifamily	22.5	
PG&E	Single Family	22.3	
Lighting - CFLs	Multifamily	29.3	
SDG&E	Single Family	26.1	
Refrigerators	Multifamily	695.4	
SCE	Single Family	711.6	
Refrigerators	Multifamily	644.7	
PG&E and SDG&E	Single Family	644.7	

Per-unit savings for measures affecting electric weather-sensitive end uses are presented in Table E-3. Impacts are higher for single-family dwellings, except for the SCE evaporative cooler measure, where more multifamily dwellings are located in warmer climate zones. Heating savings are highest for PG&E, which has the coldest climate, followed by SCE, and then SDG&E. (SDG&E ceiling insulation values were used for SCE because SCE had too few participants receiving ceiling insulation [six dwellings] to develop independent estimates.) Cooling savings tend to be highest again for PG&E, followed generally by SDG&E, and then SCE. Again impacts are driven by location of participants in the various climate zones in California.

Table E-3
Annual Per-Unit Savings – Weather-Sensitive Electric Measures – kWh per Year

Measure	Dwelling Type	SCE		PG&E		SDG&E	
		Heating	Cooling	Heating	Cooling	Heating	Cooling
Caulking	Multifamily	4.7	2.6	6.0	4.5	3.7	2.3
	Single Family	6.9		8.5	8.2	5.1	2.7
Ceiling Insulation	Multifamily	34.4		59.0	70.2	34.4	
	Single Family	50.1		81.6	110.7	50.1	43.5
Duct Sealing	Multifamily						
	Single Family					13.4	7.3
Evaporative Cooler Covers	Multifamily			18.7			
	Single Family			24.0		15.8	
Building Envelope Repair	Multifamily	14.8	5.1	20.8	14.1	12.9	7.0
	Single Family	21.6		29.3	25.1	18.0	8.1
Weather stripping	Multifamily	4.2	1.7	6.1	4.5	3.7	2.4
	Single Family	6.2		8.5	8.2	5.2	2.8
Evaporative Coolers	Multifamily		618.1		384.2		
	Single Family		397.2		446.2		

Table E-4 shows per-unit savings for measures affecting gas heating. As with weather-sensitive electric measures, impacts are largest for single-family dwellings. PG&E, with the coldest climate, shows the largest per-unit savings. SDG&E and SoCalGas impacts are fairly similar, but vary based on the location of participants who received particular measures.

Table E-4
Annual Per-Unit Savings – Weather-Sensitive Natural Gas Measures – Therms per Year

Measure	Dwelling Type	PG&E	SDG&E	SoCalGas
Caulking	Multifamily	1.6	2.0	0.7
	Single Family	3.3	2.5	1.5
Ceiling Insulation	Multifamily	18.7	11.0	9.6
	Single Family	34.2	16.9	18.7
Duct Sealing	Multifamily			
	Single Family		1.8	
Evaporative Cooler Covers	Multifamily	4.0		4.1
	Single Family	7.2	4.3	8.1
Building Envelope Repair	Multifamily	4.6	3.8	2.2
	Single Family	8.8	5.5	4.4
Weather stripping	Multifamily	1.6	2.0	0.7
	Single Family	3.3	2.7	1.4
Furnace Filters	Multifamily	2.3		
	Single Family	4.7		
Furnace Repair	Multifamily	42.9	16.0	
	Single Family	42.9	23.0	24.4
Furnace Replacement	Multifamily	147.2		
	Single Family	147.2	84.3	110.1

This report documents the impact evaluation of the statewide Low Income Energy Efficiency (LIEE) Program for Program Year (PY) 2000. The participating utilities are Southern California Edison Company (SCE), Pacific Gas and Electric Company (PG&E), San Diego Gas and Electric Company (SDGE), and Southern California Gas Company (SoCalGas). Southern California Edison Company (SCE) managed this project on behalf of all the California investor-owned utilities in accordance with the Joint Recommendation on the Program Year 2000 (PY2000) LIEE Program Shareholder Incentive Mechanism.

1.1 PROGRAM DESCRIPTION

Since the early 1980s, California's investor-owned natural gas and electricity utilities have offered programs designed to support energy services to the low-income community. These programs have taken a number of forms. At this time, all four utilities administer both California Alternate Rates for Energy (CARE) and LIEE programs. The LIEE program consists of weatherization, energy-efficiency, and energy education components.

The LIEE program provides assistance to low-income customer groups throughout the state. The assistance consists of free installation of energy-efficiency measures, energy education, and repair and/or replacement of space heating and evaporative cooling equipment. The program serves an important equity objective in assisting customers who are highly unlikely or unable to participate in other residential conservation programs because of income constraints. This program allows income-eligible customers to receive the benefits of energy conservation without the hardship of making cash investments.

The utilities use a variety of community-based organizations (CBOs) and local contractors to locate and recruit households that qualify for program participation, i.e., households whose annual incomes are less than the low-income weatherization income limits established by the California Public Utilities Commission. Staff from these entities receive training by each utility or utility representatives in the installation of ceiling insulation and other conservation measures.

Measures included in the LIEE program (across all service territories but not by all utilities) include:

- Evaporative cooler installation (permanent or portable)
- Relamping
- Weatherization
- Energy education
- Refrigerator replacement
- Porch lamp fixture replacement
- Furnace repair and replacement.

Table 1-1 lists the PY2000 LIEE measures that are applicable for one or more of the utilities, and Table 1-2 summarizes PY2000 LIEE Program accomplishments.

**Table 1-1
PY2000 LIEE Program Installed Measures**

Attic access install	Door weatherstrip	Glazing compound	Thresholds installed
Attic access weatherstrip	Eave/soffit vents	HWD lights	Thresholds repaired
Attic insulation	Energy education	Low-flow showerheads	Turbine vents
Attic venting	Evaporative cooler cover	Miscellaneous (nails, tape)	Utility gaskets
MHR	Evaporative cooler	Mobile home repairs	Wall repairs
Caulking	Exterior CFL fixtures	Pipe insulation	Water heater blankets
CFLs	Faucet aerators	Plumbing repair	Weatherization
Cover plates replaced	Furnace filters	Refrigerator replacement	Weatherstrip
CVA	Furnace repair	Roof jack vents	Window area repair
Doors repaired	Furnace replacement	Shower adapters	Window pane replacement
Doors replaced	Glass replacement	Switch/outlet gaskets	Window repair

**Table 1-2
PY2000 LIEE Program Reported Accomplishments**

Units	Measure	PG&E	SDG&E	SCE	SCG	Total
# of households	In-Home Energy Education	42,038	13,896	46,032	22,617	¹ <101,966
	Energy Education Workshops	n/a	26,575	n/a	11,621	38,196
	Weatherization	32,730	9,893	1,347	22,617	66,587
# of units	Gas Furnace	494	7,893 ²	-	2,996	11,383
	Refrigerator	4,317	714	2,613	-	7,644
	Evaporative Cooler	1,623	21	2,083	-	3,727
	CFLs	141,774	27,413	200,341	-	369,528

Notes:

¹ The total number of households that received energy education in PY2000 and are budgeted to receive energy education in PY2001 do not include SoCalGas energy education, because there may be overlap between homes in SoCalGas/SCE overlap territory that received energy education from both utilities. The extent of the overlap was not examined as part of this effort.

² SDG&E performs furnace services on all gas furnaces assessed; both minor repairs and major repairs are provided.

1.2 EVALUATION OBJECTIVES

The impact evaluation is intended to quantify first-year load impacts by developing savings estimates for PY2000 installed measures based on billing analysis. These savings estimates will be used to assess energy savings and update forecasting assumptions. In addition, the billing analysis of PY2000 installed measures is a formal part of the filing requirements of the PY2000 earnings assessment.

1.3 EVALUATION APPROACH

The impact evaluation utilizes a billing analysis approach. Monthly household electricity and natural gas consumption, both before and after program intervention, are modeled in regression equations as a function of program participation variables and other explanatory variables such as weather, dwelling type, and survey variables. Engineering-based program savings variables were incorporated into the analysis for some measures to develop more detailed measure-specific results than could be obtained from a simple billing analysis.

Two types of billing analysis models were developed and integrated to assess impacts:

- Models using all PY2000 program participants with adequate billing data plus a control group consisting of all PY1998 participants with adequate billing data; and
- Models using a subset of PY2000 program participants who were administered a telephone survey.

The primary reason for collecting telephone survey data for a subset of participants is to remove uncertainty about end-use fuel types present in the home and to assess non-program changes at the home that could affect energy consumption and mask program savings.

1.4 REPORT ORGANIZATION

The remainder of this report is organized as follows:

- Section 2, Methodology, provides a description of the research methods and data used in the study
- Section 3, Analysis and Results, presents the study findings and results
- Appendix A provides a copy of the telephone survey instrument and response frequencies
- Appendix B contains M&E Protocols Table 6 and Table 7.

2.1 OVERVIEW

This section presents the study methodology. First, the study sample design is presented, followed by a discussion of the data collection activities. Finally, the analysis approach is presented.

A billing analysis approach was used to develop savings estimates for the LIEE program. Two sets of electric and gas regression models were developed and integrated to provide program impact results: models based on all program participants who had adequate billing data, and models utilizing a subset of 1,000 participants who were administered a telephone survey.

2.2 SAMPLE DESIGN

The impact evaluation sample design was used to select program participants for telephone surveys that were used to augment the billing analysis. In the sample design, each utility was allocated 250 sample points. These points were spread among various measure types and dwelling types.

The goal of the sample design was to include enough observations for each different measure type and dwelling type for a successful billing analysis. Therefore, sample cells are set up in a way to increase the likelihood that all relevant measures are included in the analysis, and minimum cell quotas are set to ensure that enough observations for each measure-type/dwelling-type combination are covered.

The following subsections present the sample design for each utility. In each subsection, we first show counts of dwellings where each different measure type was installed. We then show results aggregated into more manageable segments for the sample design. Dwelling types were aggregated into two or three groups for each utility—single family (including mobile homes), multi-family, and “unknown.” Finally, we show target sample counts of dwellings in the aggregated segments. Finally, we compare dwelling counts, by segment, for the total program population, the portion of the population that had sufficient billing data for our analysis, and the portion of the population that were surveyed.

2.2.1 SCE

Table 2-1 presents counts of SCE dwellings that received measures as part of the PY2000 LIEE program, based on tracking system data. Counts are presented by each dwelling type provided in the tracking system. For SCE, there were a total of 51,263 participating homes in the PY2000 program. The most common measures were lighting measures, installed in over 45,000 homes. Evaporative coolers and refrigerators were installed in over 2,000 homes each. The

weatherization measures were installed in 1,347 homes. About 60 percent of the homes participating in the SCE program were multifamily dwellings (condominiums and apartments).

Table 2-1 also shows the aggregate measure and dwelling type categories that were used to facilitate the sample design.

Table 2-1
SCE PY2000 LIEE Program Accomplishments
Tracking System Counts of Dwellings that Received Different Measures

Aggregate Measure Segment	Detailed Measure Category	Dwelling Type					Total
		Single Family Segment		Multifamily Segment			
		Single Family	Mobile Home	Condo-minium	Apartment (2-4 units)	Apartment (5+ units)	
Water Heating	Water Heater Blanket			1	8	41	50
	Pipe Insulation				7	11	18
	Faucet Aerators	5	1	2	44	209	261
Other	Low Flow Showers	11	2	91	111	971	1,186
Weatherization	Caulking	6	1	105	82	883	1,077
	Weather stripping	11	2	107	127	1100	1,347
	Building Envelope Repair	8	1	103	112	1062	1,286
	Switch/Outlet Gaskets	11	2	107	124	1083	1,327
	Ceiling Insulation	1				5	6
	Sun Screen	4		43	18	342	407
Evap Coolers	Evaporative Coolers	1,639	394	23	3	24	2,083
Refrigerators	Refrigerators	732	214	321	136	1,210	2,613
Lighting	Relamping	4,281	1,556	3,499	1,048	7,060	17,444
	Program=7000 (lighting)	6,179	3,174	3,693	1,696	13,034	27,776
Total Dwellings*		11,759	5,089	7,552	2,972	21,635	48,977

* Reflects unique homes in the program. Columns do not sum to the total because multiple measures may be installed in the same home.

Table 2-2 shows dwelling counts for the aggregate SCE segments, and Table 2-3 shows the SCE sample design. For the sample design, each segment was initially allocated 20 sample points. Then the remaining sample points were allocated proportionately, based on the number of dwellings that received a particular measure.

Table 2-2
SCE: Dwelling Counts by Aggregate Segments

Measure Type	Dwelling Type		
	Single Family	Multiple Family	Total
Water Heating	6	259	265
Other Weatherization	13	1,333	1,346
Evaporative Coolers	2,033	50	2,083
Refrigerators	946	1,667	2,613
Lighting	15,190	30,030	45,220
Total Dwellings*	16,848	32,129	48,977

* Reflects unique homes in the program. Columns do not sum to the total because multiple measures may be installed in the same home.

Table 2-3
SCE: Sample Design

Measure Type	Dwelling Type		
	Single Family	Multiple Family	Total
Water Heating	29		29
Other Weatherization	31		31
Evaporative Coolers	44		44
Refrigerators	26	32	58
Lighting	37	51	88
Total			250

Segment Assignment, Bill Screening, and Completed Surveys

To select the sample for telephone surveys, each dwelling participating in the LIEE program had to be assigned to a unique sampling segment. (Recall in Tables 2-1 and 2-2, many dwellings received multiple measures; this is why the columns in these tables do not sum to the total number of dwellings.) Assignment of each dwelling to a unique segment avoids the potential for sampling a given dwelling more than once.

To accomplish this assignment, dwellings that received measures from the least populous measure group were allocated to the first segment. Thus, all SCE program participants who received water heating measures (see Table 2-2) were allocated to the water heating segment. Then the remaining dwellings that received measures from the next least populous measure group were assigned to the next segment. Thus, all SCE participants who received “other weatherization” measures but who did not receive any water heating measures were assigned to the “other weatherization” segment. This process continued until all the dwellings were assigned to a unique segment.

Next, each dwelling was screened for adequate billing data. The screening criteria included the following:

- The dwelling could be matched to the billing system
- The dwelling had an individually metered account
- There were all nonnegative bill reads associated with the account
- The account had adequate pre-installation and post-installation billing data (12 months pre, and 9 months post).

Finally, the telephone survey house attempted to attain the targeted sample sizes for each segment. In several cases, the target sample size could not be attained and the remaining surveys were reallocated to other segments.

Table 2-4 summarizes the segment assignment, bill screening, and surveying process. The target sample is also included in the table for cross-reference to Table 2-2.

Table 2-4
Segment Assignment, Bill Screening, and Completed Surveys

Measure Type	Dwelling Type	Total Dwellings	Screened Dwellings	Target Sample Size	Completed Surveys
Water Heating	All	265	107	29	29
Other Weatherization	All	1,082	362	31	32
Evaporative Coolers	All	2,083	1,041	44	45
Refrigerators	Single Family	946	542	26	26
Refrigerators	Multifamily	1,667	801	32	32
Lighting	Single Family	13,856	6,441	37	37
Lighting	Multifamily	29,078	10,239	51	49
Total		48,977	19,533	250	250

2.2.2 PG&E

Table 2-5 presents counts of PG&E dwellings that received measures as part of the PY2000 LIEE program, based on tracking system data. Counts are presented by each dwelling type provided in the tracking system.

For PG&E, there were 36,259 participating homes in the PY2000 program. Predominant measures installed in over 80 percent of the PG&E participants' homes are low-flow showerheads, faucet aerators, caulking, weatherstripping, building envelope repair, switch outlet gaskets, and CFLs. Dwelling type was not indicated by PG&E's PY2000 program administrator for about half of the PG&E participants. The remaining homes were split about evenly between single-family and multi-family dwellings.

Table 2-5 also shows the aggregate measure and dwelling-type categories that were used to facilitate the sample design.

Table 2-5
PG&E PY2000 LIEE Program Accomplishments
Tracking System Counts of Dwellings that Received Different Measures

Aggregate Measure Segment	Detailed Measure Category	Dwelling Type				Total
		Single Family Segment		MF Segment	Unknown Segment	
		Single Family	Mobile Home	Multi family	Unknown	
Furnace Repair/Replace	Furnace Replace	8	1	1	41	51
	Furnace Repair	127	7	4	342	480

Total Dwellings*		9,301	656	7,747	18,763	36,467

* Reflects unique homes in the program. Columns do not sum to the total because multiple measures may be installed in the same home.

Table 2-6 shows dwelling counts for the aggregate PG&E segments, and Table 2-8 shows the PG&E sample design. Because of the large number of PG&E segments resulting from the large “unknown” dwelling type category, each segment was initially allocated 9 sample points. Then the remaining sample points were allocated proportionately, based on the number of dwellings that received a particular measure. Finally, the “Furnace Repair/Replace,” “Refrigerator,” and “Evaporative Cooler” segments were augmented and sample was reduced for the other segments to ensure each measure received adequate sample points for the billing analysis.

Table 2-6

2.2.3 SDG&E

Table 2-9 presents counts of SDG&E dwellings that received measures as part of the PY2000 LIEE program, based on tracking system data. Counts are presented by each dwelling type provided in the tracking system.

For SDG&E, there were a total of 14,973 participating homes in the PY2000 program. Predominant measures installed in over 80 percent of the SG&E participants' homes are building envelope repair measures and CFLs. Most of the participating dwellings were mobile homes and multi-family units.

Table 2-9 also shows the aggregate measure and dwelling type categories that were used to facilitate the sample design.

2.2.4 SoCalGas

Table 2-13 presents counts of SoCalGas dwellings that received measures as part of the PY2000 LIEE program, based on tracking system data. Counts are presented by each dwelling type

provided in the tracking system. For SoCalGas, there were a total of 23,842 participating homes in the PY2000 program. Predominant measures installed in over 75 percent of the SoCalGas participants' homes are caulking, weather stripping, building envelope repair, low-flow showerheads, faucet aerators, and switch/outlet gaskets. About two-thirds of the participating dwellings were single-family units.

Table 2-13 also shows the aggregate measure and dwelling type categories that were used to facilitate the sample design.

2.3 DATA COLLECTION

This subsection outlines the data collection activities and data sources that were used for the project. A number of different data elements were used to support the billing analysis, including:

- Telephone survey data
- Program tracking system data
- Utility billing data
- Weather data.

Sources for these data are discussed next.

2.3.1 Telephone Surveys

Telephone surveys were conducted to support the impact analysis. The telephone surveys focused on four main categories:

1. Measure verification: whether or not the measures are installed
2. Household information: holdings of key appliances, number of residents, home size
3. Household changes: additions/removals of major appliances and changes in the number of residents, additional conservation
4. Process questions: satisfaction with the program and the measures.

A copy of the telephone survey instruments is provided in Appendix A.

Survey Process

Gilmore Research, an experienced survey research firm, was subcontracted to conduct telephone surveys of program participants. Gilmore has been used on previous evaluation projects and has demonstrated the capability to administer surveys in both English and Spanish, a requirement for this project given the relatively large number of Hispanic participants.

XENERGY provided the survey instrument and customer sample, in electronic form, to Gilmore. The survey instrument was programmed into a CATI (computer-assisted telephone interviewing) system. The CATI system ensures that the survey is filled out consistently and that complete survey contact records are retained.

The survey instrument was pretested on 20 participants prior to finalization. Minor adjustments were required to the instrument to improve the flow of the survey and to reduce overall length of the survey.

At the completion of the survey, Gilmore Research returned the completed survey databases (in dbase format) to XENERGY. XENERGY loaded the data into PC-SAS datasets for incorporation into the analyses.

2.3.2 Program Tracking System Data

The utilities each provided program tracking data for each of the their programs. These data included:

- Customer identification (name, address, phone number, account number, etc.);
- Measure installation dates;
- Measure descriptions and quantities;
- Customers demographics (age category, language type, income); and some
- Home and end-use information (home size, home type, presence of electric heating, electric water heating, and air conditioning).

All data were sufficiently documented and organized to facilitate incorporation into the analyses.

2.3.3 Billing Data

The utilities provided XENERGY with two separate extracts of billing data. First, an initial extract of data were provided for all program participants for use in the survey sample development. Second, a final extract of monthly billing data for the January 1999—October 2001 period were provided for all participants for use in the billing analysis. The data spanned a period sufficient to comply with the M&E Protocols.

Billing data consisted of kWh and therm consumption, electric and gas revenue amounts, meter read dates, and days in the billing period.

2.3.4 Weather Data

The utilities provided daily average temperature data for each available weather station for the January 1990—October 2001 period. This period covered the dates included in the billing histories and also provided a 10-year period to construct “average” temperature conditions for use in normalizing savings estimates. A mapping of each customer to the appropriate weather station also was provided.

Heating degree-day and cooling degree-day variables were calculated on a daily basis. These variables were aggregated to each customer’s billing month based on individual meter read dates.

2.4 ANALYSIS APPROACH

A billing-analysis approach was used to estimate measure savings. This methodology used multivariate regression models to estimate household energy use in terms of program participation, while controlling for changes in weather, household characteristics, and other market/demographic conditions.

The analysis was implemented using monthly data (in a pooled time series/cross-sectional model). The general form of the monthly model is:

$$Use_{it} = \mu_i + \tau_t + \beta_1 PART_{it} + \sum_{j=2}^n \beta_j X_{ij} + \varepsilon_{it}$$

where:

Use_{it}	=	Average daily electric or gas use for customer i in time period t
$PART_{it}$	=	Program participation indicator for customer i in time period t equal to one after program implementation and zero prior to implementation
X_{ij}	=	Other explanatory variables that could affect energy use
μ_i	=	Dummy variable, 1 for customer i , 0 otherwise
τ_t	=	Dummy variable, 1 for time period t , 0 otherwise
β 's	=	Estimated parameters
ε_{it}	=	Error term.

The parameter in the above equation is β_1 , the coefficient reflecting impacts of program participation and installing measures. For the analysis, multiple PART variables can be included to develop impact results by different measure groups. The program savings variables can be interacted with other customer attributes (such as housing type, type of air conditioner, and weather variables) to develop savings estimates that vary by key customer group. In an alternative specification, the PART variable can be replaced by engineering-based estimates of program savings (in kWh or therms per day). Then the β_1 coefficient represents an estimate of the program or measure realization rate, the fraction of the savings estimate realized in customer bills.

The customer-specific level variables, μ_i , and the time-specific level variables, τ_t , are included to control for “fixed-effects,” the stable but unmeasured characteristics of each customer and time period. The fitting of these two sets of fixed effects eliminates two important potential sources of intercorrelation among the model residuals. The customer-specific variables adjust for each customer’s base use, facilitating the calibration to customer bills. We will explore models both with and without these fixed effects.

The X_{itj} variables can include weather variables (interacted with the presence of space cooling and/or electric space heating), non-program factors that affect energy consumption (such as family additions, major appliance purchases, additions of cooling capacity, non-program conservation, etc.), and customer classification variables (housing type, weather zone, etc.). In addition, energy prices may be useful in the model to capture customer responses to increasing energy bills. These variables help control for non-program factors that can obscure the estimates of program savings.

Two types of electric and gas billing analysis models were developed for this study. The first set of models was developed using data for all Program Year (PY) 2000 participants who had adequate billing data for inclusion in the study (a minimum of 12 months of pre-installation data and 9 months of post-installation data). A control group consisting of PY 1998 participants with adequate billing data was included in the analysis to help control for non-program effects.

A second set of models was developed for a subset of 1,000 PY 2000 participants who were administered a telephone survey. The survey data were collected in an attempt to develop a better understanding of measure installations, key household appliance holdings, and non-program changes that occurred in the home.

3.1 OVERVIEW

This section describes the billing analysis models that were developed for this evaluation and presents the impact estimate results that were obtained from the models.

3.2 BILLING ANALYSIS

The following topics are covered in the billing analysis discussion:

- Development of initial measure savings estimates
- Billing analysis of all participants with adequate billing data
- Billing analysis of participants with survey data
- Discussion and integration.

3.2.1 Initial Measure Savings Estimates

As discussed in Section 2, initial measure savings estimates can be used as explanatory variables in the billing analysis. This approach was especially useful for the weatherization and water heating measures, where it was possible to have multiple measures targeted at a single end use, but it was difficult to include too many measure variables into a single regression equation.

Table 3-1 summarizes the initial measure savings estimates used for key weatherization measures in the analysis. Savings estimates were developed from two key sources: the LIEE Bill Savings Report,¹ and the previous LIEE impact evaluation for the 1998 program.² In addition, an initial savings estimate of 560 kWh per year was utilized for the PG&E and SDG&E refrigerator replacement measures. Customer-specific refrigerator savings estimates were provided by SCE, averaging 1,304 kWh per home.

¹ *Joint Utility Low Income Energy Efficiency Program Costs and Bill Savings Report*, Final Report, February 1, 2001 (Revised as of March 5, 2001).

² Parris, Kenneth, *First Year Load Impact Study of 1998 Low Income Energy Efficiency Programs for Pacific Gas and Electric Company, San Diego Gas and Electric Company, Southern California Edison Company, Southern California Gas Company*, April 2000.

**Table 3-1
Initial Weatherization Measure Savings Estimates**

Measure	Electric - kWh per Year			Gas - Therms per Year	
	AC	Space Heat	Water Heat	Space Heat	Water Heat
Attic Insulation	130	200		25	
Caulking	10	20		2	
Weatherstripping	10	20		2	
Building Repairs	30	70		6	
Furnace Filters				3	
Evaporative Cooler Covers		60		5	
Duct Sealing	25	50		2	
Low Flow Showerheads			247		10
Water Heater Blankets			198		8
Pipe Insulation			140		3
Faucet Aerators			50		1.5

For the electric impact models, we were not able to statistically determine variations in weatherization measures between single-family and multifamily dwellings, as model parameters were unstable and provided unrealistic results in some cases. Thus, based on results from the 1998 LIEE Program evaluation, multifamily savings were constrained to equal 70 percent of single-family savings for space conditioning measures and 85 percent of single-family savings for water heating measures.

For other measures (furnace repair, furnace replacement, CFLs, and evaporative coolers), a simple program indicator (1.0 or 0.0) variable was used in the analysis.

3.2.2 Billing Analysis Using All Available Participants

The first set of billing analysis models was developed utilizing all PY 2000 participants with adequate billing data. In addition, a control group was included in the analysis to control for non-program effects. Participants from the PY 1998 program were utilized as the control group because they were considered to be similar to the PY 2000 participants but did not have program measures installed in the January 1999 to October 2001 period.

Because customers in the billing analysis were not surveyed, an additional analysis was conducted to assess the presence of major end uses (air conditioning, space heating by fuel, and water heating by fuel).

The major end-use ownership indicators were assigned to the sample using the average monthly usage profiles. Appliance ownership indicators were assigned to households that passed various usage criteria. For gas samples, space and water heating ownership indicators were developed. For the electric samples, space heating, water heating, and air conditioning indicators were created. Baseline codes were used to create the space and water heating indicators for SCG. PG&E had information on central air conditioning. Analysis of average monthly usage was undertaken to determine appliance ownership for the remaining utilities.

In the case of gas space heating, customers using more than 30 therms in the winter (December and January) months or customers whose winter use was more than 50 percent greater than summer (July and August) use were assigned as gas space heating customers. Analysis of summer use was employed to determine gas water heating. Customers whose monthly summer usage was 10 or more therms were assigned as gas water heating.

Electric space heating and water heating ownership were determined by looking at winter period use relative to spring season (April and May). Customers whose winter and spring electric use exceeded 800 kWh per month were assigned to have both electric space heating and water heating. Customers whose winter monthly usage was over 700 kWh and more than 25 percent higher than spring monthly kWh were assigned electric space heating. Customers whose spring monthly usage was greater than 650 kWh were assigned electric water heating. In the case of air conditioning, customers whose summer monthly use exceeded 800 kWh were assigned electric air conditioning.

The introduction of key end uses was required to provide structure to the billing analysis models. For example, only customers with air conditioning were modeled to be affected by cooling degree-days variables and to have air conditioning savings affects due to weatherization measures. Similarly, customers with gas water heating showed gas savings for water heating measures, and customers with electric water heating showed electric savings for the water heating measures.

Electric Model

Electric model results are presented in Table 3-2. The model has an R^2 of 0.81, which indicates that just over 80 percent of the variation in monthly kWh per day is explained by the model. This is a relatively high R^2 for models of this type. All key variables are statistically significant (with t-statistics over 2.0). Shaded rows indicate variables that are used to identify program impacts. Each variable is described as follows (with variable names in brackets):

- **[Evaporative cooling × CDD]**—A dummy variable indicating customers who received evaporative cooler measures interacted with cooling degree-days. This term identifies base cooling load for customers who received evaporative coolers through the program.
- **[Evaporative cooling × CDD × POST]**—The evaporative cooler dummy variable interacted with cooling degree-days and a post-retrofit dummy variable that takes on the value of 0.0 in periods prior to the program install date and 1.0 in periods after the program install date. This term identifies savings related to installation of program evaporative coolers.
- **[Electric heating × HDD]**—A dummy variable indicating the presence of electric heating interacted with heating degree-days. This term identifies base heating load for single-family homes.
- **[Electric heating × HDD × multifamily]**—The electric heating dummy variable interacted with heating degree-days and a dummy variable for multifamily dwellings. This term combined with the prior term identifies base heating load for multi-family homes.

- **[Electric heating × HDD × POST × weatherization savings]**—The electric heating dummy variable interacted with heating degree-days, the post-retrofit dummy variable, and an initial estimate of space conditioning weatherization savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies electric heating savings from the installation of weatherization measures.
- **[AC × CDD]**—A dummy variable indicating the presence of air conditioning interacted with cooling degree-days. This term identifies base cooling load for single-family homes.
- **[AC × CDD × multifamily]**—The air conditioning dummy variable interacted with cooling degree-days and a dummy variable for multifamily dwellings. This term combined with the prior term identifies base cooling load for multi-family homes.
- **[AC × CDD × POST × weatherization savings]**—The air conditioning dummy variable interacted with cooling degree-days, the post-retrofit dummy variable, and the initial estimate of space conditioning weatherization savings. This term identifies air conditioning savings from the installation of weatherization measures.
- **[POST × refrigerator savings, (PG&E, SDG&E)]**—The post-retrofit dummy variable interacted with an initial estimate of refrigerator savings. This estimate, 560 kWh per year, does not vary by participant. This term identifies savings from the program installation of new refrigerators in the PG&E and SDG&E service areas.
- **[POST × refrigerator savings (SCE)]**—The post-retrofit dummy variable interacted with an initial estimate of refrigerator savings. This savings estimate varies by customer, based on estimated energy usage of the new and replace refrigerator and averages 1,304 kWh per year. This term identifies savings from the program installation of new refrigerators.
- **[POST × number of CFLs distributed]**—The post-retrofit dummy variable interacted with the number of CFLs that the tracking system indicates were provided to the customer. This term identifies program CFL savings.
- **[POST × number of CFLs distributed, if less than 4]**—The post-retrofit dummy variable interacted with the number of CFLs that the tracking system indicates were provided to the customer, if the customer received less than four CFLs. This term identifies additional program CFL savings (above those captured in the previous variable) for customer who received fewer bulbs. Evidence has shown that per-bulb CFL savings are higher for households who receive fewer bulbs because customers tend to install CFLs in fixtures they use most frequently. As more bulbs are distributed, they tend to be installed in fixtures are receive less frequent use, resulting in lower per-bulb savings.
- **[Electric water heat × POST × water heating savings]**—A dummy variable indicating the presence of electric water heating interacted with the post-retrofit dummy variable and an initial estimate of water heating measure savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies electric water heating savings from the installation of program measures.

- **[Customer fixed effects]**—These variables allow for a different intercept term for each participant, accounting for variations in bill size due to dwelling and household effects that are outside of the program.
- **[Monthly dummy variables]**—These variables account for unexplained seasonality of use and non-program variations over time. The coefficients on the monthly dummy variables for 2001 are generally lower than the coefficients on corresponding dummy variables for 2000, reflecting increased customer conservation in response to the California energy crisis.

Natural Gas Model

Gas model results are presented in Table 3-3. The model has an R^2 of 0.74, which indicates that about 74 percent of the variation in monthly therms per day is explained by the model. Again this R^2 indicates a relatively good model fit. All key variables are statistically significant (with t-statistics over 2.0). Shaded rows indicate variables that are used to identify program impacts. Each variable is described as follows (with variable names in brackets):

- **[Gas heating × (1-furnace replace/repair) × HDD]**—A dummy variable indicating the presence of gas heating interacted with a variable to exclude customers who received furnace replace or repair measures and heating degree-days. This term identifies base heating load for single-family homes.
- **[Gas heating × (1-furnace replace/repair) × HDD × multifamily]**—The gas heating dummy variable interacted with the furnace replace/repair dummy variable, heating degree-days, and a dummy variable for multifamily dwellings. This term combined with the prior term identifies base heating load for multi-family homes.
- **[Gas heating × HDD × POST × weatherization savings]**—The gas heating dummy variable interacted with heating degree-days, the post-retrofit dummy variable, and an initial estimate of space conditioning weatherization savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies gas heating savings for single-family dwellings from the installation of weatherization measures.
- **[Gas heating × HDD × multifamily × POST × weatherization savings]**—The gas heating dummy variable interacted with heating degree-days, a multifamily dummy variable, the post-retrofit dummy variable, and an initial estimate of space conditioning weatherization savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term when combined with the prior term identifies gas heating savings for multifamily dwellings from the installation of weatherization measures.
- **[Gas heating × furnace replace × HDD]**—A dummy variable indicating the presence of gas heating interacted with a variable denoting customers who received furnace replacements and heating degree-days. This term identifies base heating load for customers who received new furnaces.
- **[Gas heating × furnace replace × HDD × POST]**—The gas heating dummy variable interacted with the furnace replacement dummy variable, heating degree-days, and the

post retro-fit dummy variable. This term is designed to identify savings for customers who received new furnaces, but the positive sign on the coefficient indicates that this measure was correlated with increased load, most likely because many customers do not have working furnaces prior to the retrofit.

- **[Gas heating × furnace repair × HDD]**—A dummy variable indicating the presence of gas heating interacted with a variable denoting customers who received furnace repairs and heating degree-days. This term identifies base heating load for customers whose furnaces were repaired.
- **[Gas heating × furnace repair × HDD × POST]**—The gas heating dummy variable interacted with the furnace repair dummy variable, heating degree-days, and the post retro-fit dummy variable. This term is designed to identify savings for customers whose furnaces were repaired, but similar to the furnace replacement term, the positive sign on the coefficient indicates that this measure was correlated with increased load because many customers do not have working furnaces prior to the retrofit.
- **[Gas water heat × POST × water heating savings]**—A dummy variable indicating the presence of gas water heating interacted with the post-retrofit dummy variable and an initial estimate of water heating measure savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies gas water heating savings for single-family dwellings from the installation of program measures.
- **[Gas water heat × multifamily × POST × water heating savings]**—A dummy variable indicating the presence of gas water heating interacted with a multifamily dummy variable, the post-retrofit dummy variable, and an initial estimate of water heating measure savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term combined with the prior term identifies gas water heating savings for multifamily dwellings from the installation of program measures.
- **[Customer fixed effects]**—These variables allow for a different intercept term for each participant, accounting for variations in bill size due to dwelling and household effects that are outside of the program.

Note that monthly dummy variables were not included in the gas model. Due to the large seasonal component of gas use, the monthly dummy variables tended to interfere with the estimation of gas space heating savings.

3.2.3 Billing Analysis Using Surveyed Participants

The second set of billing analysis models were developed utilizing a subset of 1,000 PY 2000 participants with adequate billing data who were administered a telephone survey. For this group, survey data were used to ascertain the presence of major end uses (air conditioning, space heating by fuel, and water heating by fuel). In addition, survey data were utilized to obtain variables that tend to influence home energy use (square footage of the home, number of people in the home, and whether someone is generally home during the day).

The survey was also used to develop equipment-related variables. A key component in the analysis of furnace repair and replace measures was the determination of whether or not the customer's furnace was working prior to the program retrofit. A similar issue was addressed for customers who received evaporative coolers.

For CFLs, we attempted to construct an engineering-based lighting savings variable using customer-reported CFL installations levels and customer estimates of lighting hours of use. However, we were not able to incorporate this variable into the electric regression model because this variable came in with the wrong sign (implying CFL installations caused an increase in energy use). It is likely that the dwelling-specific CFL savings estimates were correlating positively with customer size (as larger households with larger energy bills were also reporting more lighting hours of use, which is a key component of the CFL savings variable). The negative savings estimates developed from this variable (due to the estimated coefficient having the wrong sign) contradicted the savings estimates developed from the simpler CFL variables used in the final models presented in this section. We chose to use the simpler CFL variables because they provided more intuitive results.

Electric Model

Electric model results for surveyed participants are presented in Table 3-4. The model has an R^2 of 0.79 indicating that about 79 percent of the variation in monthly kWh per day is explained by the model. Most key variables are statistically significant (with t-statistics over 2.0). Shaded rows indicate variables that are used to identify program impacts. Each variable is described as follows (with variable names in brackets):

- **[Evaporative cooling × SQFT × CDD × unit working pre-program]**—A dummy variable indicating customers who received evaporative cooler measures interacted with dwelling square footage, cooling degree-days, and a dummy variable indicating whether a cooling unit was working prior to the retrofit. This term identifies base cooling load for customers who cooled their homes prior to the retrofit and received evaporative coolers through the program.
- **[Evaporative cooling × SQFT × CDD × unit working pre-program × POST]**—The evaporative cooler dummy variable interacted with dwelling square footage, cooling degree-days, the dummy variable indicating whether a cooling unit was working prior to the retrofit, and a post-retrofit dummy variable that takes on the value of 0.0 in periods prior to the program install date and 1.0 in periods after the program install date. This term identifies savings related to installation of program evaporative coolers for customers who had a working unit prior to the retrofit.
- **[Evaporative cooling × SQFT × CDD × unit not working pre-program × POST]**—The evaporative cooler dummy variable interacted with dwelling square footage, cooling degree-days, a dummy variable indicating whether a cooling unit was not working prior to the retrofit, and the post-retrofit dummy variable. This term identifies load increases related to installation of program evaporative coolers for customers who did not have a working unit prior to the retrofit.
- **[Electric heating × SQFT × HDD]**—A dummy variable indicating the presence of electric heating interacted with dwelling square footage and heating degree-days. This term identifies base heating load for customers who are not generally home during the day.
- **[Electric heating × SQFT × HDD × home weekdays]**—The electric heating dummy variable interacted with dwelling square footage, heating degree-days, and a dummy variable indicating someone is generally home on weekdays. This term combined with the prior term identifies base heating load for homes that are generally occupied during the day on weekdays.
- **[Electric heating × SQFT × HDD × POST × weatherization savings]**—The electric heating dummy variable interacted with heating degree-days, dwelling square footage, the post-retrofit dummy variable, and an initial estimate of space conditioning weatherization savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies electric heating savings from the installation of weatherization measures.

- **[AC × SQFT × CDD]**—A dummy variable indicating that the presence of air conditioning interacted with dwelling square footage and cooling degree-days. This term identifies base cooling load for customers who are not generally home during the day.
- **[AC × SQFT × CDD × home weekdays]**—The air conditioning dummy variable interacted with cooling degree-days and a dummy variable indicating someone is generally home on weekdays. This term combined with the prior term identifies base cooling load for homes that are generally occupied during the day on weekdays.
- **[AC × SQFT × CDD × POST × weatherization savings]**—The air conditioning dummy variable interacted with dwelling square footage, cooling degree-days, the post-retrofit dummy variable, and the initial estimate of space conditioning weatherization savings. This term identifies air conditioning savings from the installation of weatherization measures.
- **[POST × refrigerator savings, (PG&E, SDG&E)]**—The post-retrofit dummy variable interacted with an initial estimate of refrigerator savings. This estimate, 560 kWh per year does not vary by participant. This term identifies savings from the program installation of new refrigerators in the PG&E and SDG&E service areas.
- **[POST × refrigerator savings (SCE)]**—The post-retrofit dummy variable interacted with an initial estimate of refrigerator savings. This savings estimate varies by customer, based on estimated energy usage of the new and replace refrigerator and averages 1,304 kWh per year. This term identifies savings from the program installation of new refrigerators.
- **[POST × number of CFLs distributed]**—The post-retrofit dummy variable interacted with the number of CFLs that the tracking system indicates were provided to the customer. This term identifies program CFL savings.
- **[POST × number of CFLs distributed, if less than 4]**—The post-retrofit dummy variable interacted with the number of CFLs that the tracking system indicates were provided to the customer, if the customer received fewer than four CFLs. This term identifies additional program CFL savings (above those captured in the previous variable) for customer who received fewer bulbs. Evidence has shown that per-bulb CFL savings are higher for households who receive fewer bulbs because customers tend to install CFLs in fixtures they use most frequently. As more bulbs are distributed, they tend to be installed in fixtures are receive less frequent use, resulting in lower per-bulb savings.
- **[Electric water heat × number in home × POST × water heating savings]**—A dummy variable indicating the presence of electric water heating interacted with the number of people living in the home, the post-retrofit dummy variable, and an initial estimate of water heating measure savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies electric water heating savings from the installation of program measures.
- **[Customer fixed effects]**—These variables allow for a different intercept term for each participant, accounting for variations in bill size due to dwelling and household effects that are outside of the program.

- **[Monthly dummy variables]**—These variables account for unexplained seasonality of use and non-program variations over time.

Natural Gas Model

Gas model results are presented in Table 3-5. The model has an R^2 of 0.70 which indicates that about 70 percent of the variation in monthly therms per day is explained by the model. Most variables and all key variables are statistically significant (with t-statistics over 2.0). Shaded rows indicate variables that are used to identify program impacts. Each variable is described as follows (with variable names in brackets):

- **[Gas heating × (1-furnace replace/repair) × SQFT × HDD]**—A dummy variable indicating that the presence of gas heating interacted with a variable to exclude customers who received furnace replacement or repair measures, dwelling square footage, and heating degree-days. This term identifies base heating load for single-family homes where someone is not home during weekday days.
- **[Gas heating × (1-furnace replace/repair) × SQFT × HDD × home weekdays]**—The gas heating dummy variable interacted with the furnace replace/repair dummy variable, dwelling square footage, heating degree-days, and a dummy variable indicating someone is home during the day. This term combined with the prior term identifies base heating load for single-family homes where someone is home during the day on weekdays.
- **[Gas heating × (1-furnace replace/repair) × SQFT × HDD × multifamily]**—The gas heating dummy variable interacted with the furnace replace/repair dummy variable, dwelling square footage, heating degree-days, and a dummy variable for multifamily dwellings. When this term is combined with the first heating term, it identifies base heating load for multifamily homes where someone is not generally home during weekday days. When this term is combined with the two prior terms, it identifies base heating load for multifamily homes where someone is home during weekday days.
- **[Gas heating × SQFT × HDD × POST × weatherization savings]**—The gas heating dummy variable interacted with heating degree-days, dwelling square footage, the post-retrofit dummy variable, and an initial estimate of space conditioning weatherization savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies gas heating savings for single-family dwellings from the installation of weatherization measures.
- **[Gas heating × SQFT × HDD × multifamily × POST × weatherization savings]**—The gas heating dummy variable interacted with building square footage, heating degree-days, a multifamily dummy variable, the post-retrofit dummy variable, and an initial estimate of space conditioning weatherization savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term, when combined with the prior term, identifies gas heating savings for multifamily dwellings from the installation of weatherization measures.
- **[Gas heating × furnace replace × SQFT × HDD × unit working pre-program]**—A dummy variable indicating the presence of gas heating interacted with a variable denoting customers who received furnace replacements, dwelling square footage, heating degree-

days, and a dummy variable indicating the home had a working furnace prior to the retrofit. This term identifies base heating load for customers who had a working furnace prior to the retrofit and received new furnaces through the program.

- **[Gas heating × furnace replace × SQFT × HDD × unit working pre-program × POST]**—The gas heating dummy variable interacted with the furnace replacement dummy variable, dwelling square footage, heating degree-days, the dummy variable indicating there was a working pre-retrofit furnace, and the post retro-fit dummy variable. This term identifies savings for customers who had working furnaces prior to the retrofit and received new furnaces.
- **[Gas heating × furnace replace × SQFT × HDD × unit not working pre-program × POST]**—The gas heating dummy variable interacted with the furnace replacement dummy variable, dwelling square footage, heating degree-days, a dummy variable indicating there was not a working pre-retrofit furnace, and the post retro-fit dummy variable. This term identifies usage increases related to installation of program furnaces for customers who did not have a working furnace prior to the retrofit.
- **[Gas heating × furnace repair × SQFT × HDD × unit working pre-program]**—A dummy variable indicating the presence of gas heating interacted with a variable denoting customers who received furnace repairs, heating degree-days, and a dummy variable indicating there was a working furnace prior to the repair. This term identifies base heating load for customers with working pre-retrofit furnaces whose furnaces were repaired through the program.
- **[Gas heating × furnace repair × SQFT × HDD × unit working pre-program × POST]**—The gas heating dummy variable interacted with the furnace repair dummy variable, heating degree-days, the dummy variable indicating a working pre-retrofit furnace, and the post retro-fit dummy variable. This term identifies savings for customers who had working furnaces prior to the retrofit and received furnace repairs.
- **[Gas heating × furnace repair × SQFT × HDD × unit not working pre-program × POST]**—The gas heating dummy variable interacted with the furnace repair dummy variable, heating degree-days, a dummy variable indicating there was not a working furnace prior to the repair and the post retro-fit dummy variable. This term identifies usage increases related to program furnaces repairs for customers who did not have a working furnace prior to the repair.
- **[Gas water heat × number in home × POST × water heating savings]**—A dummy variable indicating the presence of gas water heating interacted with the number of people in the home, the post-retrofit dummy variable, and an initial estimate of water heating measure savings using combinations of values from Table 3-1, depending on the particular measures installed in each home. This term identifies gas water heating savings for single-family dwellings from the installation of program measures.
- **[Gas water heat × number in home × multifamily × POST × water heating savings]**—A dummy variable indicating the presence of gas water heating interacted with the number of people in the home, a multifamily dummy variable, the post-retrofit dummy variable, and an initial estimate of water heating measure savings using combinations of values from Table 3-1, depending on the particular measures installed in

each home. This term combined with the prior term identifies gas water heating savings for multifamily dwellings from the installation of program measures.

- **[Customer fixed effects]**—These variables allow for a different intercept term for each participant, accounting for variations in bill size due to dwelling and household effects that are outside of the program.

Note that monthly dummy variables were not included in the gas model. Due to the large seasonal component of gas use, the monthly dummy variables tended to interfere with the estimation of gas space heating savings.

3.2.4 Billing Analysis Discussion and Integration

In general, it was felt that the billing analysis models using all available participants provided better results than the models using surveyed participants. The all-participant models included many more observations and provided better statistical fit than the surveyed-participant models.

The all-participant models were better able to capture more realistic savings from refrigerator replacement and CFL measures, while the surveyed-participant models tended to provide much lower-than-expected CFL savings and higher-than-expected refrigerator replacement savings. The all-participant models also provided more realistic variation in gas water heating savings between single-family and multifamily dwellings—with multifamily savings equal to about 85 percent of single-family savings. The surveyed-participant models showed single-family savings for gas water heating measures to be about five times as large as the multifamily savings.

The primary area where the all-participant models performed worse than the surveyed-participant models was in the development of savings for furnace repair and replace measures. For these measures, participants often had furnaces that were not working prior to the program treatment. Thus, the all-participant models tended to associate an increase in natural gas use with the presence of furnace measures. For the surveyed participants, we were able to identify the customers who did not have a working furnace prior to the program and net them out of the savings calculation since these customers were now receiving substantial non-energy-savings benefits. Thus the surveyed-participant models tended to provide better estimates for the energy savings component of the furnace measures.

For calculation of impacts, the all-participant model results were utilized for all measures except the furnace repair and furnace replacement measures. For these measures, results of the surveyed-participant models were used.

3.3 IMPACT ESTIMATES

3.3.1 Calculation of Impacts

Impact estimates were developed using the billing analysis models discussed above. The models were simulated for each household under two conditions:

1. Assuming no LIEE program measures were installed
2. Assuming all LIEE program measures were installed as tracked.

All non-program variables, such as household characteristics and weather, are held constant for the simulations. The resulting differences between the simulations provide estimates of measure savings. Since normal weather variables are used in the simulation process, weather-sensitive measure impacts reflect normal weather conditions.

Customer-specific impacts are then averaged to provide program unit savings. Weights were developed to ensure that the sample of customers reflected the program population for the averaging process.

Next, measure counts were developed for each relevant combination of measure, dwelling type, and fuel. For weatherization measures, this involved determining each participant's heating fuel type and whether or not space cooling was present. For water heating measures, this involved determining each participant's fuel type.

Finally, program impacts are estimated by multiplying unit impacts time measure counts.

3.3.2 Impact Estimates

Tables 3-6 through 3-9 below provide estimates of program impacts by utility. Non-weather-sensitive measure unit impacts are constant across utilities. Weather-sensitive impacts (weatherization measures, evaporative cooler measures, furnace repair and replacement

measures, and evaporative cooler measures) vary by utility due to climatic differences among the service territories. Unit savings are expressed on a per-home basis, except for CFLs, which are expressed on a per-bulb basis.

SCE

SCE impacts are presented in Table 3-6. Overall, the PY2000 LIEE program is estimated to be saving 7.5 GWh per year in the SCE area. Key measures include CFLs with savings of 4.5 GWh, new refrigerators with savings of 1.8 GWh, and evaporative coolers with savings of 0.8 GWh. Higher evaporative cooler unit savings for multifamily dwellings versus single-family dwelling is primarily the results of climatic conditions facing the multifamily and single-family participants.

PG&E

PG&E impacts are presented in Table 3-7. Overall, the PY2000 LIEE program is estimated to be saving 8.8 GWh per year and 1.0 million therms per year in the PG&E area. Similar to SCE, key electricity saving measures include CFLs with savings of 3.2 GWh, new refrigerators with savings of 2.8 GWh, and evaporative coolers with savings of 1.1 GWh. The major gas saving measures include ceiling insulation (0.215 Mth), building repairs (0.168 Mth), and low-flow showerheads (0.208 Mth).

SDG&E

SDG&E impacts are presented in Table 3-8. Overall, the PY2000 LIEE program is estimated to be saving 1.3 GWh per year and 0.2 million therms per year in the SDG&E area. Key electricity saving measures include CFLs with savings of 0.7 GWh and new refrigerators with savings of 0.5 GWh. The major gas saving measures include low-flow showerheads (0.050 Mth), building repairs (0.044 Mth), and furnace replacements (0.021 Mth).

3.3.3 Statistical Precision of the Impact Estimates

Tables 3-10 through 3-13 present, by utility, the 90 percent and 80 percent confidence intervals associated with the unit savings estimates. The confidence intervals were calculated from the standard errors of the regression coefficients associated with the measure impact variables. As the tables show, most of the confidence intervals are small relative to the unit estimates, which indicates a fairly high degree of statistical precision.

3.3.4 Comparison to Initial Utility Estimates

This subsection compares evaluation savings results with initial utility estimates as found in the LIEE Program Bill Savings Report. Non-weather-sensitive measure savings are compared first, followed by weather-sensitive measure savings.

Non-Weather-Sensitive Measures

Non-weather-sensitive electric impact results for the evaluation are compared to utility estimates in Table 3-14. Gas results are compared to utility estimates in Table 3-15. Blank cells in each table indicate that no utility estimate was provided for PY2000 in the Bills Savings Report. Also, in each table realization rates are provided in parentheses below the utility estimate. The realization rates represent the fraction of the initial estimates that were realized in customer bills. They are calculated by dividing the evaluation results by the utility estimate.

For the measures affecting electric end uses, the utility water heating measure estimates were closest to the impact results. Utility refrigerator estimates for PG&E and SDG&E were lower than the impact result, but SCE's refrigerator impact estimate was much higher. Also, for SCE the refrigerator unit impact estimate of 1,776 kWh per year for the Bill Savings Report overstates the average unit impact estimate of 1,304 kWh per year provided by SCE in their tracking data. It appears that the 1,776 kWh figure was actually the estimate of average pre-retrofit refrigerator usage and not the kWh savings estimate.

For lighting, all three utilities' estimates were considerably higher than the impact results. Note, the evaluation could not separate out interior and exterior CFL savings because only SCE provided an indicator for customers who received porch lights. Thus, the evaluation results reflect average CFL savings for all installed interior and exterior bulbs. The evaluation estimates imply average daily lighting hours equal to about 1.3 hours per delivered bulb, while the utility numbers are higher at about 3 hours per day per bulb for PG&E, 3.5 hours for SCE, and 4.5 hours for SDG&E. Given, the fairly large number of bulbs given out to each household (averaging over four bulbs per home for PG&E and SCE and over two bulbs per home for SDG&E), it is reasonable to expect relatively low hours of use per bulb. Per-bulb savings for SDG&E were estimated to be somewhat higher than for SCE and PG&E, reflecting the fact that SDG&E gave out fewer bulbs to each household, and bulbs were most likely placed in higher-usage fixtures.

Table 3-14
Comparison of Non-Weather-Sensitive Electric Impacts– kWh per Year

Measure	Dwelling Type	Evaluation	SCE ¹	PG&E	SDG&E
Faucet Aerators	Multifamily	41.2			
	Single Family	48.4			
Low Flow Showerheads	Multifamily	203.3		247.2 (0.82)	174.0 (1.17)
	Single Family	239.2		247.2	174.0 (1.37)
Water Heater Blankets	Multifamily	163.0		197.8 (0.82)	138.0 (1.18)
	Single Family	191.8		197.8	138.0 (1.39)
Water Heater Pipe Wrap	Multifamily	115.3		53.0 (2.18)	
	Single Family	135.6		53.0 (2.56)	
Lighting - CFLs SCE	Multifamily	22.8	45.7 (0.50)		
	Single Family	22.4	45.7 (0.49)		
Porch CFLs SCE	Multifamily	22.8	204.1 (0.11)		
	Single Family	22.4	204.1 (0.11)		
Lighting - CFLs PG&E	Multifamily	22.5		57.8 (0.39)	
	Single Family	22.3		57.8 (0.39)	
Porch CFLs PG&E	Multifamily	22.5		70.0 (0.32)	
	Single Family	22.3		70.0 (0.32)	
Lighting - CFLs SDG&E	Multifamily	29.3			77.0 (0.38)
	Single Family	26.1			77.0 (0.34)
Porch CFLs SDG&E	Multifamily	29.3			181.0 (0.16)
	Single Family	26.1			181.0 (0.14)
Refrigerators SCE	Multifamily	695.4	1,776.0 (0.39)		
	Single Family	711.6	1,776.0 (0.40)		
Refrigerators PG&E and SDG&E	Multifamily	644.7		542.0 (1.19)	402.0 (1.60)
	Single Family	644.7		542.0 (1.19)	402.0 (1.60)

¹ SCE weatherization impacts are not reported by measure; total savings of 536 kWh per year are assumed.

For non-weather-sensitive gas measures, evaluation impacts for multifamily dwellings were estimated to be much lower than single-family impacts. Given this effect, the utility estimates tend to be fairly comparable to evaluation results for single-family homes (with the exception of faucet aerators), but the utility multifamily estimates tend to be much higher than the evaluation results. PG&E's estimates tend to exceed the evaluation results by the largest margin.

Table 3-15
Comparison of Non-Weather-Sensitive Gas Impacts – Therms per Year

Measure	Dwelling Type	Evaluation	PG&E	SDG&E	SoCalGas
Faucet Aerators	Multifamily	0.9	3.5 (0.26)		3.5 (0.26)

	Single Family	7.3	13.2 (0.55)	6.0 (1.22)	7.0 (1.04)
Water Heater Pipe Wrap	Multifamily	1.8	4.0 (0.45)		2.6 (0.69)
	Single Family	2.7	4.0 (0.68)		2.6 (1.04)

Weather-Sensitive Measures

For weather-sensitive measures, the comparison between evaluation results and utility estimates is presented by utility because the evaluation results vary by utility due to climatic differences.

The comparison between the evaluation and SCE is presented in Table 3-16. Because SCE does not report weatherization impacts by measure and does not offer furnace measures, the only weather-sensitive measure available for comparison is evaporative coolers. The evaluation evaporative cooler results come in at 88 percent of SCE's estimate for multifamily dwellings and 56 percent of SCE's estimate for single-family dwellings.

Table 3-16
Comparison of Weather-Sensitive Impacts - SCE

Measure	Dwelling Type	Heating kWh per Year		Cooling kWh per Year

	Single Family			397.2	705.3 (0.56)

¹ SCE weatherization impacts are not reported by measure; total savings of 536 kWh per year are assumed.

The comparison between the weather-sensitive evaluation results and PG&E's estimates is presented in Table 3-17. For most weather-sensitive measures, the evaluation results tend to nearly equal or exceed PG&E's estimates. The major exceptions are for electric heating impacts involving caulking, weatherstripping, building repair, and ceiling insulation measures. Also,

PG&E has assumed electric energy savings for their furnace filter measure while the evaluation found no savings.

Table 3-17
Comparison of Weather-Sensitive Impacts – PG&E

Measure	Dwelling Type	Heating kWh per Year		Cooling kWh per Year		Heating Therms per Year	
		Evaluation	PG&E	Evaluation	PG&E	Evaluation	PG&E

	Single Family			446.2	353.6 (1.26)		

The comparison between the weather-sensitive evaluation results and SDG&E's estimates is presented in Table 3-18. The evaluation results were higher than SDG&E's estimates for all electric savings measures except weatherstripping. For gas savings measures, SDG&E's

estimates tend to exceed the evaluation results, with the exception of multifamily caulking and weatherstripping and single-family furnace replacement.

Table 3-18

	Single Family				130.0		

¹ SDG&E did not break out electric weatherization savings into space heating and cooling components. For comparison to evaluation results, it was assumed that all electric weatherization savings applied to space heating.

The comparison between the weather-sensitive evaluation results and SoCalGas's estimates are presented in Table 3-19. For most measures, the SoCalGas single-family estimates are similar to

the evaluation results, while the SoCalGas multifamily estimates are about double the evaluation results. The exceptions are for evaporative cooler covers and furnace replacement, where the evaluation results are considerably higher than the SoCalGas estimates.

SURVEY INSTRUMENT AND FREQUENCIES

INTRO:

IF PERSON NO LONGER LIVES THERE OR THERE'S NO ONE BY THAN NAME AT THIS PHONE NUMBER, CODE 19 - THANK & TERMINATE

Hello, my name is ____, and I'm calling on behalf of<util1>. May I speak to<cont>?

IF NEEDED: I'm calling from the Gilmore Research Group.

REINTRODUCE IF NECESSARY: Our records show that in <MONTH> of <YEAR> your household participated in the <PROGM>. As part of this program, improvements were made to your home to make it more energy efficient. Do you remember participating in this program?

IF DON'T KNOW/NOT SURE, SAY: These improvements may have included: <ecc> <refrg> <water> <ducts> <nonci> <ceili> <frepr> <frepl> <ec> <cfl>

N = 1000 100%

Q1:

We are conducting a survey of customers who participated to learn about their energy usage and experience with the program. This information will be used to help improve services for <util1> customers. All information will remain confidential. IF NEEDED: This survey will take about 10 minutes.

Q4:

I'm going to read off a list of things that might have been installed in your home as part of the <PROGRAM NAME>. Please tell me if these were installed, and whether they are still in place and working. The first is . . .

A. Number of Electric measures installed by participants		7,397	(Total dwellings with electric space heating receiving space heating measures)								
A. Number of Gas measures installed by participants		61,133	(Total dwellings with gas space heating receiving space heating measures)								
C. Number of measures installed by Comp Group		na									
7. Market Segment Data											
B. Distribution of participants by CEC Climate zone		See next page									

Table 6 - Space Heating, Page 1

B.2 TABLE 7

B.2.1 Overview Information

a. Study Title and Study ID Number

Study Title: *Impact Evaluation of the 2000 Statewide Low Income Energy Efficiency (LIEE) Program*

Study ID No: 576

b. Program, Program Year and Program Description

Program: Statewide LIEE Program

Program year: 2000

Program description: The Statewide LIEE Program provides assistance to low-income customer groups throughout the state. The assistance consists of free installation of energy-efficiency measures, energy education, and repair and/or replacement of space heating and evaporative cooling equipment. The program serves an important equity objective in assisting customers who are highly unlikely or unable to participate in other residential conservation programs because of income constraints. This program allows income-eligible customers to receive the benefits of energy conservation without the hardship of making cash investments.

c. End Uses Covered

Space cooling, space heating, water heating, lighting, refrigeration

d. Methods and Models Used

Billing analysis utilizing a pooled time-series/cross-sectional load impact regression model.

e. Participant and Comparison Group Definition

- Participant group: qualified low income customers who received program services during calendar year 2000 and had adequate billing data to support a billing analysis.
- Nonparticipant comparison group: customers who participated in the PY1998 LIEE program and who had adequate data to support a billing analysis.

f. Analysis Sample Size

Electric Model	Participants	Nonparticipants
Number of Customers	35,776	35,316
Number of Installations	35,776	0
Number of Measures	177,883	0
Number of Observations	1,175,175	1,182,343

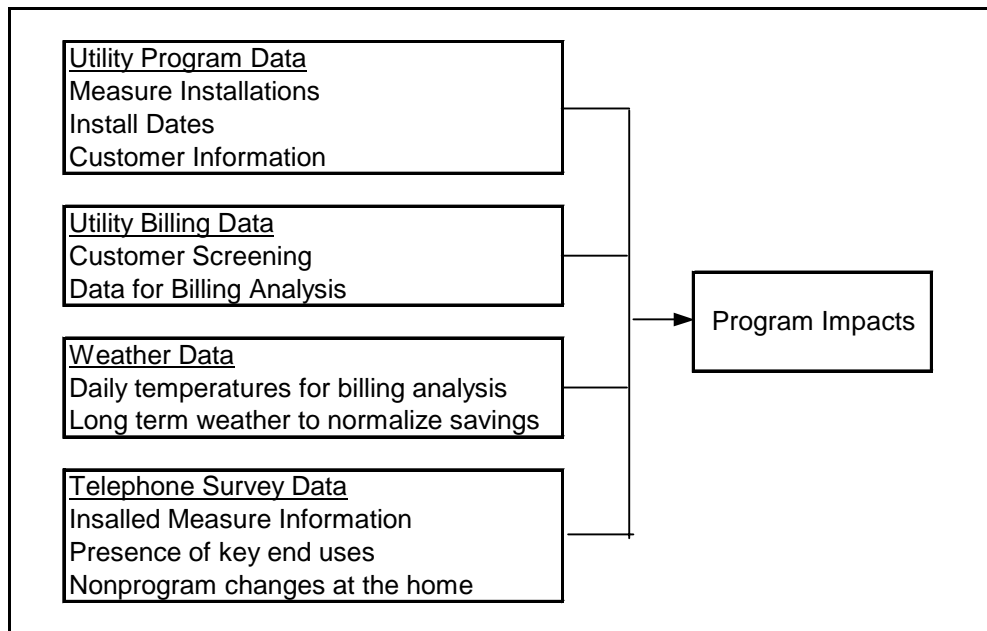

Gas Model	Participants	Nonparticipants
Number of Customers	28,261	20,566
Number of Installations	28,261	0
Number of Measures	141,236	0
Number of Observations	923,152	683,707

B.3 DATABASE MANAGEMENT

a. Flow Chart

The flow chart is presented in the following figure.

Data Flow Chart

b. Specific Data Sources

Program data: extracts from the program tacking system for PY2000 from SCE, PG&E, SDG&E, and SoCalGas.

Billing data: billing system data for the period January 1999 through October 2001 from SCE, PG&E, SDG&E, and SoCalGas.

Weather data: daily temperature data from 1990 on for multiple weather stations in the SCE, PG&E, SDG&E, and SoCalGas service areas, as provided by the utilities.

Telephone survey data: customer-reported data collected on a subset of 1,000 PY2000 program participants in a telephone survey implemented during November and December 2001.

c. Data Attrition

Data attrition is summarized in the following table.

Utility		Total Dwellings	Screened Dwellings
SCE	Starting # of Participants	48,977	
SCE	Not Individually Metered	41,098	7,879
SCE	Insufficient Pre Usage	26,034	15,064
SCE	Insufficient Post Usage	22,070	3,964
SCE	Extreme Billing Days	20,249	1,821
SCE	Early Stop Date	19,533	716
PG&E	Starting # of Participants	36,467	
PG&E	Not Resclass 1 or 2	21,816	14,651
PG&E	Insufficient Pre Usage	19,689	2,127
PG&E	Insufficient Post Usage	19,678	11
PG&E	Extreme Billing Days	19,364	314
PG&E	Early Stop Date	19,332	32
SDG&E	Starting # of Participants	14,973	
SDG&E	Not Individually Metered	7,787	7,186
SDG&E	Insufficient Pre Usage	5,756	2,031
SDG&E	Insufficient Post Usage	4,473	1,283
SDG&E	Extreme Billing Days	3,643	830
SDG&E	Early Stop Date	3,349	294
SCG	Starting # of Participants	24,271	
SCG	Not Individually Metered	21,151	3,120
SCG	Insufficient Pre Usage	16,836	4,315
SCG	Insufficient Post Usage	16,155	681
SCG	Extreme Billing Days	14,891	1,264
SCG	Early Stop Date	13,446	1,445
Total	Participants	124,688	
Total	Not Individually Metered	91,852	32,836
Total	Insufficient Pre Usage	68,315	23,537
Total	Insufficient Post Usage	62,376	5,939
Total	Extreme Billing Days	58,147	4,229
Total	Early Stop Date	55,660	2,487

d. Data Quality

Utility tracking data contained information for Application Number and Account Number. Billing data were matched to the tracking data using the Account Number. Billing data also contained a weather station ID variable that was used to merge of the appropriate weather data. Samples for the surveys included the Application Number in order to merge survey data on to the tracking data. Telephone surveys were tracked electronically using a CATI system.

e. Data Collected Specifically for the Analysis but not Used

For the electric analysis, telephone survey data was collected and analyzed. However, it was determined that the models developed using the survey data did not perform as well as models developed using the entire program population, but with no survey data. Thus, the models that included survey were not used to develop electric impacts.

B.4 SAMPLING

a. Sampling Procedures and Protocols

- Sampling frame - Participating homes with active accounts and adequate billing data; thus, for billing analyses master meter customers and customers without sufficient billing histories were excluded.
- Sampling strategy for the telephone survey: stratified random sampling
- Sampling basis: the customer
- Stratification criteria:
 - Geographical area (utility service area)
 - Dwelling type (Single family, multifamily)
 - Types of measures installed (Weatherization, CFLs, refrigerators, etc.)

b. Survey Information

Survey instruments are presented in Appendix A of the report. See the following table for response rates. Non-response bias was not addressed.

Telephone Survey Disposition Report	Total	SCE	PG&E	SDG&E	SoCal Gas

B.5 DATA SCREENING AND ANALYSIS

A. Outliers: customers with very large bills (>50,000 kWh/year for evaporative coolers and >30,000 kWh/year for weatherization) not included in the sample frame; no other outliers were eliminated.

Missing data: not a problem.

Weather adjustment: weather variables were included in regression models; savings were based on average weather.

B. Background variables: variables explaining nonprogram changes at the home were included in the regression models.

C. Data screening: See Item B3 above for the sample attrition; all sites with adequate billing data were included in models.

D. Regression statistics: statistics are provided in Tables D-1 (Evaporative cooler model) and D-2 (Weatherization model)

- E. Specification: Regression models are discussed fully in Section 2.4.2 of the Report.
 - a. Customer-specific intercept terms were used to account for cross-sectional variation.
 - b. Monthly dummy variables and site-specific nonprogram variables were included to account for time series variation.
 - c. na
 - d. na
 - e. na - model provides gross impacts; net impacts were assumed to equal gross impacts.
- F. Error in measuring variables: na
- G. Autocorrelation: monthly dummy variables were included in the electric model to minimize autocorrelation.
- H. Heteroskedasticity: customer-specific intercept terms were included to mitigate heteroskedasticity.
- I. Collinerarity: correlations among variables were reviewed; collinearity was not otherwise treated.
- J. Influent data points: not considered a problem with the large numbers of observations in the studies; no outliers were removed.
- K. Missing data: na
- L. Precision: The standard error of the regression parameters were utilized.
- M. Engineering analysis: na
- N. Net-to-gross: na

B.6 DATA INTERPRETATION AND APPLICATION

a. Net Impacts

Using the default assumption, net impacts were set equal to gross impacts.

b. Rationale

The M&E Protocols do not require a comparison group or net-to-gross analysis for the low income programs. The default assumption is that the program net-to-gross ratio is 1.0 and net impacts are equal to gross impacts.
